RoundFi

Market and Go-To-Market Strategy

Behavioral Credit Adoption Strategy for Solana

Updated: 2026-05-09 | Document 06

Less collateral through behavior. The group is not the product. Reputation is.

Executive Summary

RoundFi is not a generic consumer finance app and should not go to market as a Web3 consortium.

RoundFi's market entry should be built around a narrower, clearer wedge:

> ***DeFi users want access to capital without locking excessive collateral.***

RoundFi addresses this by turning recurring financial behavior into portable on-chain reputation that can progressively reduce collateral requirements.

The first market is not the entire global unbanked population. The first market is smaller, more realistic, and more Solana-native:

1. DeFi users who already understand collateral, borrowing, leverage, and capital efficiency.
2. Solana protocols that need better risk signals than wallet balances alone.
3. Wallets and apps that want to offer a reputation-building financial primitive.
4. Fintechs and neobanks that may eventually consume behavioral reputation through a enterprise API.

The long-term vision is larger:

> ***A behavioral reputation layer for Solana credit.***

This document explains the market, target users, go-to-market path, adoption strategy, monetization logic, and the claims RoundFi should and should not make.

1. What Market RoundFi Is Really Entering

RoundFi sits at the intersection of four markets:

Market	What it proves	How RoundFi uses it
DeFi lending	Users already borrow against collateral	Initial wedge: reduce collateral requirements through behavior
On-chain reputation	Protocols need better identity and risk signals	RoundFi turns repeated payments into portable reputation
Group-based savings behavior	Recurring financial commitment is a proven human behavior	Savings groups become the behavior-generation mechanism
Credit data infrastructure	Financial institutions pay for risk signals	Long-term enterprise reputation API / oracle

The strongest current positioning is:

> ***RoundFi is behavioral credit infrastructure for Solana.***

The protocol should not be positioned primarily as a consumer ROSCA app. The savings group is the mechanism. The reputation layer is the product.

2. The Core Market Pain

The main pain RoundFi solves is:

> ***Capital inefficiency caused by overcollateralized DeFi lending.***

In most DeFi lending markets, users cannot borrow because the protocol trusts them. They can borrow because they lock enough collateral.

This is rational for permissionless lending, but it creates a ceiling for DeFi credit.

The current model works for:

- trading;
- leverage;
- liquidity management;
- asset-backed borrowing.

But it does not work well for:

- users with less capital;
- behavior-based credit;
- credit access based on discipline;
- repeat borrowers who want better terms over time.

RoundFi's core insight is that DeFi does not need to abandon collateral immediately. It first needs a credible way to reduce collateral based on verified behavior.

3. Why DeFi Still Overcollateralizes

Overcollateralization is not a flaw in isolation. It is the mechanism that makes anonymous lending possible.

Kamino's documentation explains the logic directly: DeFi lending has no identity layer, no credit history, and no legal recourse, so collateral becomes the guarantee. A borrower must deposit more value than they borrow, and risk is managed through LTV, liquidation thresholds, borrow factors, and health monitoring.

This creates the market gap:

> ***DeFi has collateral-based risk management, but not behavior-based underwriting.***

RoundFi does not replace collateral on day one. It introduces a new signal that can make collateral requirements more dynamic over time.

4. Why the User Cares

Users do not join RoundFi because they want "reputation".

Users join because reputation produces an economic benefit.

The user benefit is:

- less collateral locked;
- better capital efficiency;
- a path toward undercollateralized credit;
- portable financial reputation;
- access to better credit terms over time.

The clearest user promise is:

> ***Complete recurring payment cycles. Build reputation. Reduce collateral requirements.***

This is the wedge that makes RoundFi understandable.

5. Initial User Segment

The initial user should not be framed as "the global unbanked".

That market is huge, but too broad for a hackathon-stage protocol. It also creates difficult onboarding problems: wallets, gas, stablecoins, education, regulation, compliance, and trust.

The better first user is:

> ***A DeFi-native user who already understands borrowing but wants to lock less collateral.***

Initial user profile

Attribute	Description
Already uses crypto	Has a Solana wallet or is willing to create one
Understands DeFi	Knows collateral, loans, stablecoins, and yield
Feels the pain	Has capital locked inefficiently or wants more borrowing power
Accepts experimentation	Open to hackathon-stage financial primitives
Can evaluate risk	More suitable than non-crypto users for early testing

This user does not need RoundFi to explain why credit matters. They need RoundFi to explain why behavior can reduce collateral.

6. Long-Term User Segments

RoundFi expands in phases.

Phase 1 - DeFi users

Users participate in savings groups to build behavioral reputation and unlock lower collateral requirements.

Phase 2 - Solana protocols and wallets

Protocols and wallets integrate the reputation layer to offer better risk segmentation, reputation displays, or credit-related features.

Phase 3 - Fintechs, neobanks, and credit applications

Financial applications query the reputation layer through an API or oracle before offering credit, limits, underwriting decisions, or risk-based terms.

7. Why Group-Based Savings Behavior Matters

Group-based savings behavior is not the product, but it validates the behavioral pattern.

People already commit to recurring group-based financial systems at massive scale.

In Brazil, the consortium system reached R$500.27 billion in commercialized credits in 2025, with 5.16 million quota sales and 12.76 million active participants according to ABAC.

This data should be used carefully.

It does not mean RoundFi is simply a regulated consortium product.

It means the underlying behavior is real:

- people commit to recurring payments;
- people coordinate financially in groups;

- people accept delayed or rotating access to capital;
- group-based financial discipline already exists at national scale.

RoundFi's innovation is not copying the regulated consortium market.

RoundFi's innovation is making recurring financial discipline verifiable, portable, and composable on-chain.

8. Why LATAM Matters

LATAM is strategically relevant because it combines:

- strong demand for alternative financial access;
- recurring group finance behavior;
- stablecoin adoption;
- inflation and currency volatility in several markets;
- large remittance and cross-border flows;
- growing crypto usage.

Chainalysis reported that Latin America recorded nearly $1.5 trillion in crypto transaction volume between July 2022 and June 2025. Brazil led the region with $318.8 billion in crypto value received, representing nearly one-third of LATAM activity.

This matters because RoundFi's long-term reputation layer becomes more useful where:

- stablecoins are already used;
- users are familiar with digital financial rails;
- traditional credit access is uneven;
- fintech adoption is strong;
- cross-border and alternative finance use cases are growing.

However, LATAM should be framed as a future expansion vector, not the only initial wedge.

The first wedge remains:

> ***Solana DeFi users who want lower collateral requirements.***

9. Why Solana Is the Right Beachhead

RoundFi requires frequent low-cost transactions.

Users must make recurring payments. The protocol must track cycles, attestations, payouts, escrow, defaults, and reputation updates.

This requires a chain where repeated micro-actions are economically viable.

Solana is well-suited because:

- fees are low;
- transactions are fast;
- wallets are widely available;
- DeFi composability is strong;
- Anchor improves developer velocity;
- SAS creates a path for portable attestations;
- Kamino provides lending and yield infrastructure;
- Switchboard provides verifiable randomness.

Solana's official documentation states that the base fee is currently 5,000 lamports per signature, and Solana educational material describes typical fees as fractions of a cent.

That cost profile matters. Behavioral credit requires repeated interactions. Expensive chains make the data-generation mechanism harder to justify.

10. Market Size Framing

RoundFi should avoid fake or overly broad TAM claims.

The right framing is layered:

1. Behavioral validation market

Group-based savings behavior already exists at large scale. Brazil's consortium market provides evidence of recurring group financial commitment, with R$500.27 billion in commercialized credits in 2025.

2. Crypto adoption market

LATAM has high and growing crypto activity. Chainalysis reported nearly $1.5 trillion in LATAM transaction volume between July 2022 and June 2025.

3. DeFi wedge

DeFi lending remains largely collateral-based. RoundFi begins with users who already understand collateral and want better capital efficiency.

4. Infrastructure market

Long term, the value is not only user fees. The value is an API / oracle layer that protocols and financial applications can query.

This keeps the market claim honest:

> ***RoundFi is not claiming to capture the entire credit market. It starts with a narrow DeFi wedge and expands into reputation infrastructure.***

11. Go-To-Market Strategy

RoundFi should go to market in three stages.

Stage 1 - Hackathon and Solana ecosystem credibility

Goal: prove execution and earn trust.

Actions:

- publish clean documentation;
- show the live demo;
- show Solscan evidence;
- show the Stress Lab;
- explain what is shipped vs roadmap;
- produce a strong technical demo video;
- engage Solana ecosystem teams.

Success metric:

- judges and builders understand that RoundFi is not only a pitch, but an executed protocol prototype.

Stage 2 - Controlled pilot users

Goal: validate user motivation.

Potential first users:

- DeFi borrowers;
- small Solana-native communities;
- hackathon testers;

- users familiar with Kamino or lending;
- users willing to test reputation-building flows.

Success metrics:

- users understand why they join;
- users complete recurring payments;
- users understand the 50/30/10 ladder;
- users see reputation as economically valuable.

Stage 3 - Protocol and fintech partnerships

Goal: prove demand for reputation data.

Targets:

- Solana lending protocols;
- wallets;
- credit apps;
- fintechs;
- neobanks;
- stablecoin apps;
- LATAM-focused crypto platforms.

Success metrics:

- one partner agrees to review the score model;
- one partner gives a letter of interest;
- one integration pilot is scoped;
- reputation is queried outside RoundFi.

12. Beachhead Positioning

RoundFi should not start with:

> ***"We are solving credit for 1.4 billion unbanked adults."***

That is too broad for the current stage.

RoundFi should start with:

> ***DeFi still forces users to overcollateralize because it cannot measure recurring financial discipline. RoundFi generates that signal on-chain.***

This is sharper, more credible, and more aligned with the product.

13. Messaging Strategy

The message should be simple:

> ***Less collateral through behavior.***

The user-facing logic is:

5. Join a savings group.
6. Complete monthly payment cycles.
7. Build on-chain reputation.
8. Unlock lower collateral requirements.

The protocol-facing logic is:

9. RoundFi generates behavioral data.

10. That data becomes portable reputation.
11. Protocols can query reputation before extending credit.
12. Better data can improve risk segmentation.

The market-facing logic is:

13. Group-based financial behavior already exists.
14. DeFi credit is still collateral-heavy.
15. Solana makes frequent participation viable.
16. RoundFi turns behavior into credit infrastructure.

14. Distribution Channels

Primary channels

- Colosseum submission page;
- GitHub repository;
- technical demo video;
- Solana builder communities;
- Superteam channels;
- X / Twitter project account;
- direct outreach to protocols.

Secondary channels

- fintech and neobank outreach;
- LATAM crypto communities;
- stablecoin-focused applications;
- developer relations teams;
- DeFi risk teams;
- Web3 credit and identity projects.

Partner categories

Partner type	Why they matter
Lending protocols	Can use reputation to adjust collateral parameters in future pilots
Wallets	Can expose reputation as a user-facing financial identity
Fintechs	Can test behavioral underwriting models
Neobanks	Can evaluate the enterprise oracle thesis
Stablecoin apps	Can support recurring payment behavior
Solana ecosystem teams	Can validate infrastructure fit

15. What RoundFi Should Not Claim

To remain credible, RoundFi should avoid these claims:

- "We solve credit for the unbanked immediately."
- "The protocol can never break."
- "We are already a production credit bureau."
- "Every protocol will read our score."
- "This is fully regulatory-cleared."

- "Yield guarantees solvency."
- "The enterprise oracle is already live."
- "The 1.4B unbanked are our first users."

Better wording:

- "We are building the foundation for behavior-based credit on Solana."
- "The system remained solvent within modeled stress conditions."
- "The enterprise oracle is the long-term business model."
- "The first users are DeFi participants seeking capital efficiency."
- "Group finance validates the behavior; RoundFi makes it composable on-chain."

16. Monetization Strategy

RoundFi has three monetization layers.

1. Participation Fees

Users may pay a small fee to participate in groups. This is the first monetization surface but should not be the only business thesis.

2. Infrastructure Yield

Idle capital can be routed through approved yield adapters. Yield can support protocol economics, but RoundFi should not depend on yield as the core business model.

3. Reputation APIs

The long-term business model is a enterprise reputation API or oracle.

Potential customers:

- lending protocols;
- fintechs;
- neobanks;
- stablecoin credit apps;
- wallets;
- risk engines;
- compliance-aware financial applications.

The reputation API is the most scalable layer because the same behavioral data can be reused by many applications.

17. GTM Milestones

Milestone 1 - Hackathon validation

- publish documentation;
- submit pitch video;
- submit technical demo;
- show live front-end;
- show devnet evidence;
- show Stress Lab;
- make the README clear.

Milestone 2 - Builder feedback

- gather feedback from Solana teams;

- ask lending protocols whether the score is useful;
- ask wallets whether reputation is user-visible value;
- refine the API design.

Milestone 3 - Controlled pilot

- launch a small devnet or testnet cohort;
- measure completed cycles;
- track user understanding;
- evaluate anti-gaming behavior;
- test whether lower collateral is enough incentive.

Milestone 4 - First partner signal

- obtain one LOI or MoU;
- define one reputation query use case;
- scope one integration with a protocol or fintech.

Milestone 5 - Mainnet beta readiness

- external audit;
- production indexer;
- SAS issuance hardened;
- regulatory review;
- partner pilot defined;
- liquidity and risk parameters reviewed.

18. Adoption Risks

Risk 1 - Users may not want to join groups

Mitigation: Position the group as the path to lower collateral, not as the final product.

Risk 2 - Protocols may not trust the score

Mitigation: Make score logic transparent, auditable, and backed by historical payment attestations.

Risk 3 - Farming or sybil behavior

Mitigation: Use recurring time-based behavior, capital commitment, identity hints where appropriate, and anti-gaming scoring rules.

Risk 4 - Regulatory uncertainty

Mitigation: Treat mainnet launch and credit integration as post-hackathon work requiring legal review.

Risk 5 - Yield volatility

Mitigation: Keep yield auxiliary. The core thesis is behavioral reputation, not yield performance.

Risk 6 - enterprise API demand is unproven

Mitigation: Prioritize early partner conversations and LOIs before assuming enterprise revenue.

19. Why This Matters for Solana

RoundFi creates a new primitive for Solana:

> ***recurring financial behavior as portable credit intelligence.***

If successful, it can improve the ecosystem by adding:

- a new reputation data layer;
- a DeFi-native credit signal;
- a path toward lower-collateral lending;
- recurring payment behavior on-chain;
- new demand for SAS attestations;
- integrations with lending, wallets, and fintech rails;
- a reason for users to build long-term financial identity on Solana.

This is why RoundFi belongs in the Solana ecosystem.

It is not only using Solana.

It is creating a Solana-native behavior data asset.

20. Recommended GTM Message

The simplest GTM message is:

> ***RoundFi helps DeFi users reduce collateral requirements by turning recurring payments into portable on-chain reputation.***

Support message:

> ***The group is not the product. Reputation is.***

User benefit:

> ***Better behavior. Lower collateral.***

Ecosystem benefit:

> ***A behavioral credit layer for Solana.***
